1 Hadoop File Formats

Format Wars: From VHS and Beta to Avro and Parquet

1.1 Feather

For light data, it is recommanded to use Feather. It is a fast, interoperable data frame storage that comes with bindings for python and R.

Feather uses also the Apache Arrow columnar memory specification to represent binary data on disk. This makes read and write operations very fast.

```
[1]: import feather
    import pandas as pd
    import numpy as np
    arr = np.random.randn(10000) # 10% nulls
    arr[::10] = np.nan
    df = pd.DataFrame({'column_{0}'.format(i): arr for i in range(10)})
    feather.write_dataframe(df, 'test.feather')
[2]: df = pd.read feather("test.feather")
    df.head()
[2]:
       column_0
                 column_1
                           column_2
                                     column_3
                                               column_4
                                                         column_5
                                                                   column_6 \
                                NaN
    0
            NaN
                      NaN
                                          NaN
                                                    NaN
                                                              NaN
                                                                        NaN
    1
       0.250020
                 0.250020
                           0.250020
                                     0.250020
                                               0.250020
                                                         0.250020
                                                                   0.250020
    2 0.167258
                0.167258 0.167258
                                    0.167258 0.167258
                                                        0.167258 0.167258
    3 1.407915
                 1.407915
                          1.407915

                           0.802632
```

1.2 Parquet file format

Parquet format is a common binary data store, used particularly in the Hadoop/big-data sphere. It provides several advantages relevant to big-data processing:

- columnar storage, only read the data of interest
- efficient binary packing
- choice of compression algorithms and encoding
- split data into files, allowing for parallel processing
- range of logical types
- statistics stored in metadata allow for skipping unneeded chunks
- data partitioning using the directory structure

1.3 Apache Arrow

Arrow is a columnar in-memory analytics layer designed to accelerate big data. It houses a set of canonical in-memory representations of flat and hierarchical data along with multiple language-bindings for structure manipulation.

https://arrow.apache.org/docs/python/parquet.html

table2 = pq.read table('example.parquet')

The Apache Parquet project provides a standardized open-source columnar storage format for use in data analysis systems. It was created originally for use in Apache Hadoop with systems like Apache Drill, Apache Hive, Apache Impala, and Apache Spark adopting it as a shared standard for high performance data IO.

Apache Arrow is an ideal in-memory transport layer for data that is being read or written with Parquet files. PyArrow includes Python bindings to read and write Parquet files with pandas.

Example:

[6]:

```
[7]: table2.to_pandas()
[7]:
       one two three
    a -1.0 foo
                  True
                 False
    b NaN bar
    c 2.5 baz
                  True
[8]: pq.read_table('example.parquet', columns=['one', 'three'])
[8]: pyarrow.Table
    one: double
    three: bool
[9]: pq.read_pandas('example.parquet', columns=['two']).to_pandas()
[9]:
       two
    a foo
    b bar
     c baz
```
